

Strings

Fall 2019

Strings

- Strings in Python can be treated as lists, in a way
- Each individual character is its own index
 - This does include white space

Loops

- Because strings can be treated as lists, loops that print lists can directly be used to print each individual character within a string
- The len function to find the length of a string also works

```
test = "Kortni Dees Neal"
```

```
for letter in test:  
    print(letter)
```

```
print()
```

```
for i in range(len(test)):  
    print(test[i])
```

K
o
r
t
n
i

D
e
e
s

N
e
a
l

Characters

- Can reference a specific character in a string
- Can also create a substring via same methodology as lists
- *Cannot* change a value of a specific index

<code>message = "Hello World"</code>	
<code>print(message[0])</code>	H
<code>print(message[3])</code>	l
<code>print(message[3:6])</code>	"lo " (includes space)
<code>print(message[6:])</code>	World
<code>print(message[:5])</code>	Hello

Searching Strings

- Can also search a string via same method of lists

```
name = "Kortni Dees Neal"
test = "Neal"

if test in name:
    print("The test variable exists in the string.")
else:
    print("The test variable does not exist in the string.")
```

String Splitting

- Strings can be split on a specified character to create a list
 - Character split on is removed entirely
- Done via `.split()` function
 - Defaults to space if nothing is specified
- Can be print or assigned to a variable

message = "Hello, my name is Kortni"	
<code>print(message.split(" "))</code>	<code>["Hello,", "my", "name", "is", "Kortni"]</code>
<code>print(message.split())</code>	<code>["Hello,", "my", "name", "is", "Kortni"]</code>
<code>print(message.split(","))</code>	<code>["Hello", " my name is Kortni"]</code>
<code>print(message.split("m"))</code>	<code>["Hello, ", "y na", "e is Kortni"]</code>

String Testing

Table 9-1 Some string testing methods

Method	Description
<code>isalnum()</code>	Returns true if the string contains only alphabetic letters or digits and is at least one character in length. Returns false otherwise.
<code>isalpha()</code>	Returns true if the string contains only alphabetic letters, and is at least one character in length. Returns false otherwise.
<code>isdigit()</code>	Returns true if the string contains only numeric digits and is at least one character in length. Returns false otherwise.
<code>islower()</code>	Returns true if all of the alphabetic letters in the string are lowercase, and the string contains at least one alphabetic letter. Returns false otherwise.
<code>isspace()</code>	Returns true if the string contains only whitespace characters, and is at least one character in length. Returns false otherwise. (Whitespace characters are spaces, newlines (<code>\n</code>), and tabs (<code>\t</code>).
<code>isupper()</code>	Returns true if all of the alphabetic letters in the string are uppercase, and the string contains at least one alphabetic letter. Returns false otherwise.

String Modification

Table 9-2 String Modification Methods

Method	Description
<code>lower()</code>	Returns a copy of the string with all alphabetic letters converted to lowercase. Any character that is already lowercase, or is not an alphabetic letter, is unchanged.
<code>lstrip()</code>	Returns a copy of the string with all leading whitespace characters removed. Leading whitespace characters are spaces, newlines (<code>\n</code>), and tabs (<code>\t</code>) that appear at the beginning of the string.
<code>lstrip(char)</code>	The <i>char</i> argument is a string containing a character. Returns a copy of the string with all instances of <i>char</i> that appear at the beginning of the string removed.
<code>rstrip()</code>	Returns a copy of the string with all trailing whitespace characters removed. Trailing whitespace characters are spaces, newlines (<code>\n</code>), and tabs (<code>\t</code>) that appear at the end of the string.
<code>rstrip(char)</code>	The <i>char</i> argument is a string containing a character. The method returns a copy of the string with all instances of <i>char</i> that appear at the end of the string removed.
<code>strip()</code>	Returns a copy of the string with all leading and trailing whitespace characters removed.
<code>strip(char)</code>	Returns a copy of the string with all instances of <i>char</i> that appear at the beginning and the end of the string removed.
<code>upper()</code>	Returns a copy of the string with all alphabetic letters converted to uppercase. Any character that is already uppercase, or is not an alphabetic letter, is unchanged.

String Search/Replace

Table 9-3 Search and replace methods

Method	Description
<code>endswith(substring)</code>	The <i>substring</i> argument is a string. The method returns true if the string ends with <i>substring</i> .
<code>find(substring)</code>	The <i>substring</i> argument is a string. The method returns the lowest index in the string where <i>substring</i> is found. If <i>substring</i> is not found, the method returns <code>-1</code> .
<code>replace(old, new)</code>	The <i>old</i> and <i>new</i> arguments are both strings. The method returns a copy of the string with all instances of <i>old</i> replaced by <i>new</i> .
<code>startswith(substring)</code>	The <i>substring</i> argument is a string. The method returns true if the string starts with <i>substring</i> .

String Examples

```
name = "Kortni Neal"

# checks if the variable is only letters
if(name.isalpha()):
    print("The name only contains letters.")
else:
    print("The name contains something other than a letter.")

# checks if the variable starts with a specific letter
if(name.startswith("K")):
    print("The first letter is K")
else:
    print("The first letter is not K")
```

The name contains something other than a letter.
The first letter is K
